Aprendizagem 2023 Homework I – Group 28

Gonçalo Bárias (ist1103124) & Raquel Braunschweig (ist1102624)

Part I: Pen and Paper

Consider the partially learnt decision tree from the dataset D. D is described by four input variables – one numeric with values in [0, 1] and 3 categorical – and a target variable with three classes.

D	y_1	y_2	y_3	y_4	$y_{ m out}$	
X 1	0.24	1	1	0	Α	$\begin{pmatrix} y_1 \end{pmatrix}$
\mathbf{x}_2	0.06	2	0	0	В	/ T
X 3	0.04	0	0	0	В	/<=0.4 \>0.4
X 4	0.36	0	2	1	C	∫ ₁ \
X 5	0.32	0	0	2	C	1
\mathbf{x}_6	0.68	2	2	1	Α	
X 7	0.9	0	1	2	Α	(y2) ?
X 8	0.76	2	2	0	Α	\mathcal{M}
X 9	0.46	1	1	1	В	/ \
X 10	0.62	0	0	1	В	=0 =1 =2
X 11	0.44	1	2	2	C	/=0 <u> </u> =1 <u> </u> =2
X 12	0.52	0	2	0	C	C A B

Figure 1: Partially Learnt Decision Tree and Dataset D from Part I

1. Complete the given decision tree using Information gain with Shannon entropy (log_2). Consider that: i) a minimum of 4 observations is required to split an internal node, and ii) decisions by ascending alphabetic order should be placed in case of ties.

The entropy of y_{out} is given by:

$$E(y_{out}|y_1 > 0.4) = p(A, y_1 > 0.4) \log_2(p(A, y_1 > 0.4)) + p(B, y_1 > 0.4) \log_2(p(B, y_1 > 0.4)) + p(C, y_1 > 0.4) \log_2(p(C, y_1 > 0.4))$$
(1)

We can calculate $E(y_{out})$:

$$E(y_{out}) = -\left(\frac{3}{7}\log_2\left(\frac{3}{7}\right) + \frac{2}{7}\log_2\left(\frac{2}{7}\right) + \frac{2}{7}\log_2\left(\frac{2}{7}\right)\right) = 1.5567$$

The next step is calculating $E(y_{out}|y_1 > 0.4, y_x)$, in which x will take the values of 2, 3 or 4:

$$E(y_{out}|y_1 > 0.4, y_x) = p(y_x = 0)E(y_{out}|y_x > 0.4, y_2 = 0) + p(y_x = 1)E(y_{out}|y_x > 0.4, y_2 = 1) + p(y_x = 2)E(y_{out}|y_x > 0.4, y_2 = 2)$$
(2)

And the information gain of variable y_x is given by

$$IG(y_x) = E(y_{out}) - E(y_{out}|y_1 > 0.4, y_x)$$
 (3)

Let's start with x = 2:

$$p(y_2 = 0, y_1 > 0.4) = \frac{3}{7}$$

$$p(y_2 = 1, y_1 > 0.4) = \frac{2}{7}$$

$$p(y_2 = 1, y_1 > 0.4) = \frac{2}{7}$$

$$E(y_{out}|y_x > 0.4, y_2 = 0) = -\left(\frac{1}{3}\log_2\left(\frac{1}{3}\right) + \frac{1}{3}\log_2\left(\frac{1}{3}\right) + \frac{1}{3}\log_2\left(\frac{1}{3}\right)\right) = 1.5849$$

$$E(y_{out}|y_x > 0.4, y_2 = 1) = -\left(\frac{0}{2}\log_2\left(\frac{0}{2}\right) + \frac{1}{2}\log_2\left(\frac{1}{2}\right) + \frac{1}{2}\log_2\left(\frac{1}{2}\right)\right) = 1$$

$$E(y_{out}|y_x > 0.4, y_2 = 2) = -\left(\frac{2}{2}\log_2\left(\frac{2}{2}\right) + \frac{0}{2}\log_2\left(\frac{0}{2}\right) + \frac{0}{2}\log_2\left(\frac{0}{2}\right)\right) = 0$$

Therefore, replacing these values on equation (2), gives us:

$$E(y_{out}|y_1 > 0.4, y_2) = \frac{3}{7} \times 1.5849 + \frac{2}{7} \times 1 + \frac{2}{7} \times 0 = 0.965.$$

Finally, we can calculate the information gain, as per (3),

$$IG(y_2) = 1.5567 - 0.965 = 0.5917$$

Now, let's calculate for x = 3:

$$p(y_3 = 0, y_1 > 0.4) = \frac{1}{7}$$

$$p(y_3 = 1, y_1 > 0.4) = \frac{2}{7}$$

$$p(y_3 = 2, y_1 > 0.4) = \frac{4}{7}$$

$$E(y_{out}|y_x > 0.4, y_3 = 0) = -\left(\frac{0}{1}\log_2\left(\frac{0}{1}\right) + \frac{1}{1}\log_2\left(\frac{1}{1}\right) + \frac{0}{1}\log_2\left(\frac{0}{1}\right)\right) = 0$$

$$E(y_{out}|y_x > 0.4, y_3 = 1) = -\left(\frac{1}{2}\log_2\left(\frac{1}{2}\right) + \frac{1}{2}\log_2\left(\frac{1}{2}\right) + \frac{0}{2}\log_2\left(\frac{0}{2}\right)\right) = 1$$

$$E(y_{out}|y_x > 0.4, y_3 = 2) = -\left(\frac{2}{4}\log_2\left(\frac{2}{4}\right) + \frac{0}{4}\log_2\left(\frac{0}{4}\right) + \frac{2}{4}\log_2\left(\frac{2}{4}\right)\right) = 1$$

Therefore, replacing these values on equation (2), gives us:

$$E(y_{out}|y_1 > 0.4, y_3) = \frac{1}{7} \times 0 + \frac{2}{7} \times 1 + \frac{4}{7} \times 1 = 0.8571.$$

Finally, we can calculate the information gain, as per (3),

$$IG(y_3) = 1.5567 - 0.8571 = 0.6996$$

Finally, let's calculate for x = 4:

$$p(y_4 = 0, y_1 > 0.4) = \frac{2}{7}$$

$$p(y_4 = 1, y_1 > 0.4) = \frac{3}{7}$$

$$p(y_4 = 1, y_1 > 0.4) = \frac{2}{7}$$

$$E(y_{out}|y_x > 0.4, y_4 = 0) = -\left(\frac{1}{2}\log_2\left(\frac{1}{2}\right) + \frac{0}{2}\log_2\left(\frac{0}{2}\right) + \frac{1}{2}\log_2\left(\frac{1}{3}\right)\right) = 1$$

$$E(y_{out}|y_x > 0.4, y_4 = 1) = -\left(\frac{1}{3}\log_2\left(\frac{1}{3}\right) + \frac{2}{3}\log_2\left(\frac{2}{3}\right) + \frac{0}{3}\log_2\left(\frac{0}{3}\right)\right) = 0.9183$$

$$E(y_{out}|y_x > 0.4, y_4 = 2) = -\left(\frac{1}{2}\log_2\left(\frac{1}{2}\right) + \frac{0}{2}\log_2\left(\frac{0}{2}\right) + \frac{1}{2}\log_2\left(\frac{1}{2}\right)\right) = 1$$

Therefore, replacing these values on equation (2), gives us:

$$E(y_{out}|y_1 > 0.4, y_4) = \frac{2}{7} \times 1.5849 + \frac{3}{7} \times 1 + \frac{2}{7} \times 0 = 0.965.$$

Finally, we can calculate the information gain, as per (3),

$$IG(y_4) = 1.5849 - 0.965 = 0.5917$$

Upon computing the information gains for each attribute, it is evident that y_3 yields the highest value of 0.6996. Consequently, it is selected as the next node, resulting in the construction of the following decision tree:

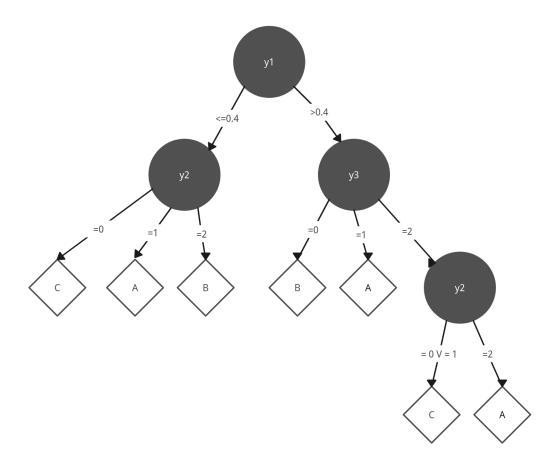

Figure 2: Decision Tree from exercise I.1

2. Draw the training confusion matrix for the learnt decision tree.

Following the learnt decision tree above, we can predict the values for each observation. For each observation, we look at the value for the first variable (y_1) and follow the branch that corresponds with its value. From the node we arrive at, we do the same thing for the next variable, and we keep doing this until we reach a leaf. The class present in this leaf will be the predicted value, while the real value is the value of y_{out} for that observation. Below we present the real values along with the predicted ones:

Finally, we can show the count of each pair of real and predicted values in a confusion matrix (e.g. 4 pairs of AA from observations x_1, x_6, x_7, x_8):

		Real			
		A	В	C	
	A	4	1	0	5
Predicted	В	0	2	0	2
	C	0	1	4	5
		4	4	4	12

3. Identify which class has the lowest training F1 score.

 $F1_{score}$ is given by the following equation:

$$F1_{score} = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}}$$
 (4)

And precision and recall are given by:

$$Precision = \frac{True \ Positives}{True \ Positives + False \ Positives}$$
 (5)

Recall =
$$\frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}}$$
 (6)

Therefore, let's start by calculating the precision for A, B and C by replacing the values on (5):

$$Precision_A = \frac{4}{4+1} = \frac{4}{5}$$

$$Precision_B = \frac{2}{2+0} = 1$$

$$Precision_C = \frac{4}{4+1} = \frac{4}{5}$$

Now, it's time to calculate the recalls for A, B and C, using the equation on (6):

$$Recall_A = \frac{4}{4+0} = 1$$

$$Recall_B = \frac{2}{2+2} = \frac{1}{2}$$

$$Recall_C = \frac{4}{4+0} = 1$$

Finally, let's calculate the $F1_{score}$, using the equation (4):

$$F1_{score}A = 2 \cdot \frac{\frac{4}{5} \cdot 1}{\frac{4}{5} + 1} = 0.8889$$

$$F1_{score}B = 2 \cdot \frac{\frac{1}{2} \cdot 1}{\frac{1}{2} + 1} = 0.6667$$

$$F1_{score}C = 2 \cdot \frac{1 \cdot \frac{4}{5}}{1 + \frac{4}{5}} = 0,8889$$

The class with the lowest training score is B, with a score of 0.6667.

4. Considering y_2 to be ordinal, assess if y_1 and y_2 are correlated using the Spearman coefficient.

To calculate the Spearman coefficient when there's rank, we have to use the following equation:

Spearman
$$(y_x, y_y) = \frac{\text{cov}(y_x, y_y)}{\sigma_{y_x} \sigma_{y_y}} = \frac{\sum_{i=1}^{n} (x_i - y_x)(y_i - y_y)}{\sqrt{\sum_{i=1}^{n} (x_i - \bar{y_x})} \sqrt{\sum_{i=1}^{n} (y_i - \bar{y_y})}}$$
 (7)

Firstly, **let's order** y_1 **and** y_2 so we can calculate the ranks and y'_1 and y'_2 :

```
\begin{aligned} ordered\_y_1 &= [0.04, 0.06, 0.24, 0.32, 0.36, 0.44, 0.46, 0.52, 0.62, 0.68, 0.76, 0.9] \\ ranks\_y_1 &= [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12] \\ y_1' &= [3, 2, 1, 5, 4, 10, 12, 11, 7, 9, 6, 8] \\ ordered\_y_2 &= [0, 0, 0, 0, 0, 0, 1, 1, 1, 2, 2, 2] \\ ranks\_y_2 &= [3.5, 3.5, 3.5, 3.5, 3.5, 3.5, 8, 8, 8, 11, 11, 11] \\ y_2' &= [8, 11, 3.5, 3.5, 3.5, 3.5, 11, 8, 3.5, 8, 3.5] \end{aligned}
```

Now, we have all we need to calculate **the Spearman coefficient** using the expression at (7). Here is the result:

$$Spearman(y_1, y_2) = 0.07966$$

5. Draw the class-conditional relative histograms of y_1 using 5 equally spaced bins in [0, 1]. Find the root split using the discriminant rules from these empirical distributions.

Blah

Part II: Programming

Consider the column_diagnosis.arff data available at the homework tab, comprising 6 biomechanical features to classify 310 orthopaedic patients into 3 classes (normal, disk hernia, spondilolysthesis).

1. Apply f_classif from sklearn to assess the discriminative power of the input variables. Identify the input variable with the highest and lowest discriminative power. Plot the class-conditional probability density functions of these two input variables.

```
import numpy as np, pandas as pd, seaborn as sns, matplotlib.pyplot as plt
from scipy.io.arff import loadarff
from sklearn.feature_selection import f_classif

# Read the ARFF file and prepare data
data = loadarff("./data/column_diagnosis.arff")
df = pd.DataFrame(data[0])
df["class"] = df["class"].str.decode("utf-8")
X, y = df.drop("class", axis=1), df["class"]
```

```
# Apply f_classif
12 f_scores, _ = f_classif(X, y)
14 # Obtains the variables with the highest and lowest discriminative power.
15 h_disc_power_var = X.columns[np.argmax(f_scores)]
16 l_disc_power_var = X.columns[np.argmin(f_scores)]
18 plt.figure(figsize=(8, 6))
20 # Plot for the highest discriminative power variable
21 for class_label in np.unique(y):
      class_data = X.loc[y == class_label, h_disc_power_var]
      sns.kdeplot(
          class_data,
24
          label=f"Class {class_label} - {h_disc_power_var}",
          linewidth=2,
      )
27
29 # Plot for the lowest discriminative power variable
 for class_label in np.unique(y):
      class_data = X.loc[y == class_label, l_disc_power_var]
      sns.kdeplot(
32
          class_data,
33
          label=f"Class {class_label} - {l_disc_power_var}",
34
          linestyle="--",
          linewidth=2,
36
      )
37
38
39 plt.xlabel("Variables")
40 plt.ylabel("Density")
42 plt.legend()
43 plt.grid(True)
44 plt.savefig("./report/class_conditional_probability.svg")
45 plt.show()
```

As you can see in the graph ahead, the highest discriminative power variable is *degree_spondilolysthesis* and the lowest discriminative power variable is *pelvic_radius*.

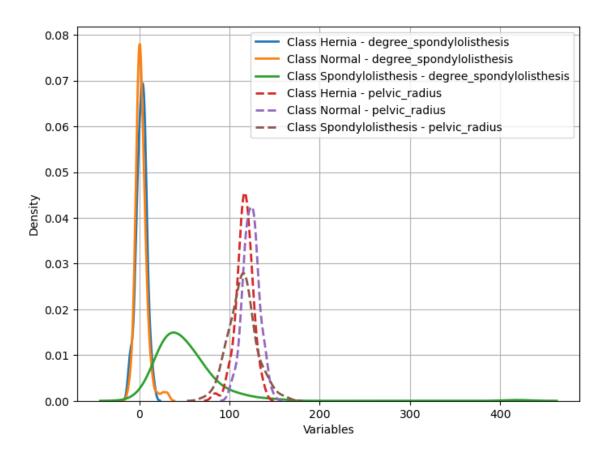

Figure 3: Class-conditional probability density functions of the highest and lowest discriminative power variables.

2. Using a stratified 70-30 training-testing split with a fixed seed (random_state=0), assess in a single plot both the training and testing accuracies of a decision tree with depth limits in $\{1, 2, 3, 4, 5, 6, 8, 10\}$ and the remaining parameters as default.

[Optional] Note that split thresholding of numeric variables in decision trees is non-deterministic in sklearn, hence you may opt to average the results using 10 runs per parameterization.

```
18 )
19
20 for depth_limit in DEPTH_LIMIT:
      # Create and fit the decision tree classifier
21
      predictor = tree.DecisionTreeClassifier(
22
          max_depth=depth_limit, random_state=0
23
24
      predictor.fit(X_train, y_train)
25
26
      # Use the decision tree to predict the outcome of the given observations
      y_train_pred = predictor.predict(X_train)
28
      y_test_pred = predictor.predict(X_test)
      # Get the accuracy of each test
31
      train_acc = metrics.accuracy_score(y_train, y_train_pred)
32
33
      training_accuracy.append(train_acc)
      test_acc = metrics.accuracy_score(y_test, y_test_pred)
34
35
      test_accuracy.append(test_acc)
36
37 plt.plot(
      DEPTH_LIMIT,
39
      training_accuracy,
      label="Training Accuracy",
40
      marker="+",
41
      color="#f8766d",
42
43
44 plt.plot(
      DEPTH_LIMIT,
45
      test_accuracy,
      label="Test Accuracy",
47
      marker=".",
      color="#00bfc4",
49
50 )
51
52 plt.xlabel("Depth Limit")
53 plt.ylabel("Accuracy")
55 plt.legend()
56 plt.grid(True)
57 plt.savefig("./report/training_testing_accuracies.svg")
58 plt.show()
```

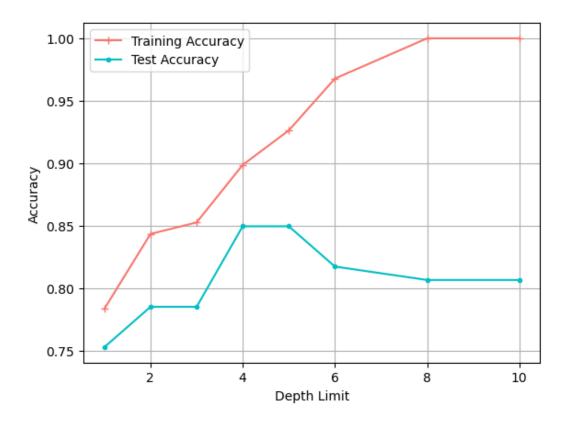

Figure 4: Accuracy of the trained decision tree, applied to both a test and training sets, for varying depth limits.

3. Comment on the results, including the generalization capacity across settings.

Blah

- 4. To deploy the predictor, a healthcare team opted to learn a single decision tree (random_state=0) using *all* available data as training data, and further ensuring that each leaf has a minimum of 20 individuals in order to avoid overfitting risks.
 - (a) Plot the decision tree.

```
import matplotlib.pyplot as plt, pandas as pd, numpy as np
from scipy.io.arff import loadarff
from sklearn.tree import DecisionTreeClassifier, plot_tree

**Read the ARFF file and prepare data
data = loadarff("./data/column_diagnosis.arff")
df = pd.DataFrame(data[0])
df["class"] = df["class"].str.decode("utf-8")
X, y = df.drop("class", axis=1), df["class"]

# Create and train the decision tree classifier
clf = DecisionTreeClassifier(random_state=0, min_samples_leaf=20)
clf.fit(X, y)

**Set style and plot the decision tree
plt.figure(figsize=(15, 10))
```

```
plot_tree(clf, filled=True, feature_names=list(X.columns),
                          class_names=list(np.unique(y)), rounded=True, fontsize=10)
19 plt.savefig("./report/decision_tree.svg")
20 plt.show()
                                                                          degree_spondylolisthesis <= 16.079
                                                                                      gini = 0.624
samples = 310
                                                                                value = [60, 100, 150]

Figure 5: Decision Tree

samples = 33 value = [0, 33, 0] class = Normal

(b) Characterize a hernia condition by identifying the hernia-conditional associations.

samples = 27 value = [3, 24, 0] class = Normal

The hernia condition can be characterized by:

- i. Spondilolysthesis degree ≤ 16.079 , sacral slope ≤ 28.136
- ii. Spondilolysthesis degree \leq 16.079, sacral slope \leq 28.136, and pelvic radius \leq 117.36

END
